Obesity in the United States is a major health issue resulting in numerous disease. It is associated with some leading causes of death, including heart disease, stroke, diabetes and is linked to an increased risk of certain types of cancer. Thus, losing weight is essential to having a healthy lifestyle. Even a modest weight loss of 5 to 10 percent of your total body weight is likely to produce health benefits. This led the FDA to make Semaglutide a weight loss medication.

What is Semaglutide?

Semaglutide is a Glucagon-like peptide (GLP-1) usually taken once weekly, that was initially approved by the FDA to treat Type-2 diabetes. Continued research of Semaglutide was conducted in larger doses for people without diabetes, long term results showed an average decrease in body mass of 15% when coupled with diet changes and exercise. This is an injectable prescription medication indicated for chronic weight management in overweight patients (BMI>27) who have a least one weight-related ailment.

How does it work?

Semaglutide is a GLP-1 receptor agonist that mimics GLP-1, an incretin hormone that our body makes when it senses there is food in the intestine. These hormones are released by the small intestine within minutes after eating and aid in the function of digestion and appetite suppression. Incretins trigger the pancreas to release the right amount of insulin when glucose levels are high helping move sugar from the blood into other body tissues where it is used for energy. It also blocks other sources of sugar. It was also discovered that the hormone aids in the function of digestion by decreasing the speed at which food leaves your stomach, leaving you feeling full longer.

How is this administered?

First month:

10 units once a week

Second month:

20 units once a week

Third month:

30 units once a week

Fourth month:

40 units once a week

Fifth month and after:

Will depend on the progress of the patient.

Is Semaglutide safe?

Yes, semaglutide is safe to use.

What are the side effects?

The most common Semaglutide side effects listed are all minor and temporary symptoms like nausea and diarrhea/constipation, headaches, and dry mouth/thirst.

However, special precautions must be observed if you have diabetes and taking Semaglutide. Blood sugar should be monitored very carefully as Semaglutide for weight loss stimulates the release of insulin and blocks other sugars from processing which can lead to low blood sugar. Semaglutide also affects how fast food leaves the stomach, so other oral medications should be used with caution.

Who should not use Semaglutide for weight loss?

Individuals with a personal or family history of thyroid cancer. Ladies who are breastfeeding or pregnant or actively trying to get pregnant. Anyone who has had pancreatitis. Type 1 diabetics or patients who have kidney or liver disease.
